Project Abstraction: Online Book Store

1. Project Description

This project is an Online Book Store system that works like a digital library. It stores all the details about the shop in one place, including a large collection of Books and Novels. The system organizes everything by Genres (like Horror or Fantasy) and Categories (like Top Rated or Discounted). It tracks the name of the author, the price of each book, and how many items are available to buy. Basically, it acts as the "brain" of the store, keeping all the inventory information organized and ready to use.

---

2. Why DBMS is used?

A DBMS is used because it is the most reliable way to handle lots of information without making a mess.

- **Organized Storage:** It keeps books, customers, and orders in separate tables so the data stays neat.
- **Quick Updates:** If a book is sold, the DBMS can update the stock number instantly.
- **Accuracy:** It makes sure that every book has a unique ID number so there is no confusion between two different books with the same name.
- **Easy Filtering:** It allows the store owner to quickly see things like "all books under $10."

---

3. How will we implement it? (Simple Steps)

1. **Identify the Data:** We list all the information we need, such as Book Titles, Author names, and Genre types.
2. **Design the Tables:** We decide how to group this information into tables (for example, a **Books** table and a **Categories** table).
3. **Build the Database:** We use simple SQL code to build these tables on the computer.
4. **Insert Information:** We add "sample data" into the tables, filling them with names of famous novels and their prices.
5. **Run Queries:** We write simple search commands to find, add, or delete books from the system to make sure it works correctly.
